Group: [4]

Software Testing - Summer 2024 - July 4, 2025 - Sibylle Schupp / Daniel Rashedi

Task 4 - Logic Coverage

a) Pick a method of your given project which contains at least **2** predicates, with one of these predicates containing at least **3** clauses. If you cannot find a three-clause-predicate in your code, you can decide to take a nested structure of *if-else* and/or nested *while* expressions instead (at least **2** levels of nesting). In that case, explain the differences for the application of your logic coverage criteria for nested structures as compared to "flat" predicates.

Answer:

The following method has been selected.

```python
def http_status_to_exit_status(http_status, follow):
    if 300 <= http_status <= 399 and not follow:
        return ExitStatus.ERROR_HTTP_3XX
    elif 400 <= http_status <= 499:
        return ExitStatus.ERROR_HTTP_4XX
    elif 500 <= http_status <= 599:
        return ExitStatus.ERROR_HTTP_5XX
    else:
        return ExitStatus.SUCCESS
```

Predicate Overview

The target function under analysis is `http_status_to_exit_status(http_status, follow)`, which maps HTTP status codes and a follow-redirect flag to specific program exit statuses.

The logical decision-making in this function is implemented using a sequence of conditional statements. The main predicate logic is as follows:

```
if 300 <= http_status <= 399 and not follow:
    return ExitStatus.ERROR_HTTP_3XX
elif 400 <= http_status <= 499:
    return ExitStatus.ERROR_HTTP_4XX
elif 500 <= http_status <= 599:
    return ExitStatus.ERROR_HTTP_5XX
else:
    return ExitStatus.SUCCESS
```

We identify three separate predicates in the code:

- **Predicate 1:** `300 <= http_status <= 399 and not follow`
  - This predicate contains **two clauses**:
    - Clause A: `300 <= http_status <= 399`
    - Clause B: `not follow`
  - This is a compound predicate connected via logical `and`.
- **Predicate 2:** `400 <= http_status <= 499`
  - A simple predicate with a single clause.
- **Predicate 3:** `500 <= http_status <= 599`

– A simple predicate with a single clause.

This function is therefore suitable for applying logic coverage criteria such as Clause Coverage (CC), Correlated Active Clause Coverage (CACC), and Inactive Clause Coverage (ICC), with Predicate 1 being the most structurally complex due to its multi-clause construction.

Flat Vs Nested Predicate

Aspect	Flat Predicate	Nested Structure
Expressiveness	One predicate with complex logic	Multiple simpler decisions across nested branches
Clause Coverage	Requires testing each sub-clause in a compound expression	Each `if` condition is tested independently
Predicate Coverage	All combinations of clause truth values affect final decision	Each decision point can be covered in isolation
MC/DC (Modified Condition/Decision Coverage)	Harder: must isolate each clause's effect on the predicate outcome	Easier: each clause corresponds to a separate decision point
Path Explosion	Rapid increase in paths due to clause combinations	More manageable: branching grows with nesting depth

Table 1: Comparison of Flat vs Nested Predicate Structures for Logic Coverage

b) Using the *pytest* coverage extension from prior tasks, measure and note down the *branch* and *line coverage* values of the existing test suite regarding your selected method.

Answer:

[Your answer]

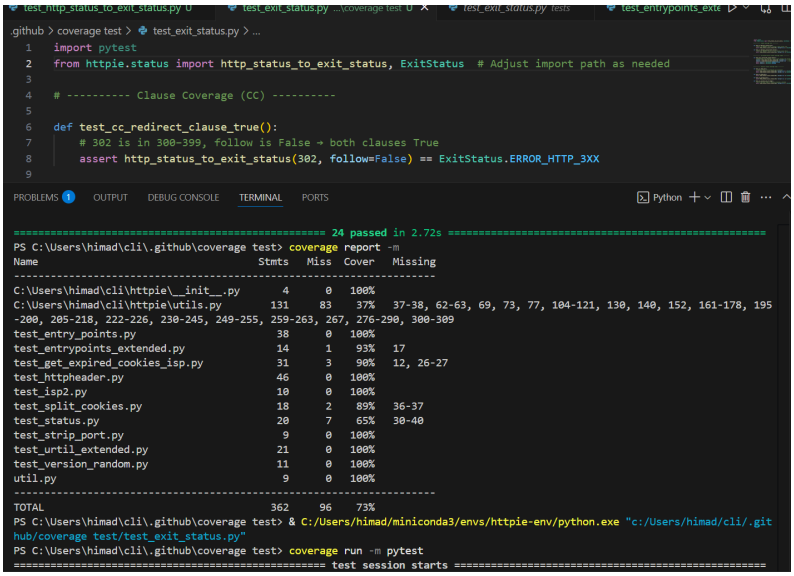

Figure 1: Screenshot of Coverage Report

c) Create a set of tests that satisfy *three* of the following logic criteria (pick one concrete criterion from each of your three selected bullet points):

- *Predicate Coverage* (PC), *Clause Coverage* (CC), *Combinatorial Coverage* (CoC)
- *Active Clause Coverage* (ACC), *General Active Clause Coverage* (GACC), *Restricted Active Clause Coverage* (RACC), *Correlated Active Clause Coverage* (CACC)
- *Inactive Clause Coverage* (ICC), *General Inactive Clause Coverage* (GICC), *Restricted Inactive Clause Coverage* (RICC)
- *Implicant Coverage* (IC)
- *Multiple Unique True Point Coverage* (MUTP), *Unique True Point and Near False Point Pair Coverage* (CUTPNFP), *Multiple Near False Point Coverage* (MNFP)

Answer:

[Your answer]

```python
import pytest
from httpie.status import http_status_to_exit_status, ExitStatus  # Adjust import path as needed

# ---------- Clause Coverage (CC) ----------

def test_cc_redirect_clause_true():
    # 302 is in -300399, follow is False → both clauses True
    assert http_status_to_exit_status(302, follow=False) == ExitStatus.ERROR_HTTP_3XX

def test_cc_redirect_clause_false_follow():
    # 302 is in -300399, follow is True → second clause False
    assert http_status_to_exit_status(302, follow=True) == ExitStatus.SUCCESS

# ---------- Correlated Active Clause Coverage (CACC) ----------

def test_cacc_controlled_clause_effect():
    # Demonstrates how changing `follow` alone changes the outcome
    result1 = http_status_to_exit_status(301, follow=False)  # Both clauses True → redirect error
    result2 = http_status_to_exit_status(301, follow=True)  # Clause B False → skips to else
    assert result1 == ExitStatus.ERROR_HTTP_3XX
    assert result2 == ExitStatus.SUCCESS

# ---------- Inactive Clause Coverage (ICC) ----------

def test_icc_http_4xx():
    # Clause A+B from first predicate are irrelevant
    assert http_status_to_exit_status(404, follow=False) == ExitStatus.ERROR_HTTP_4XX
```

```python
    assert http_status_to_exit_status(404, follow=True) ==
        ExitStatus.ERROR_HTTP_4XX

def test_icc_http_5xx():
    assert http_status_to_exit_status(503, follow=True) ==
        ExitStatus.ERROR_HTTP_5XX

def test_icc_success_2xx():
    assert http_status_to_exit_status(200, follow=True) ==
        ExitStatus.SUCCESS

def test_icc_success_out_of_range():
    # Out of defined ranges → should be treated as SUCCESS
    assert http_status_to_exit_status(600, follow=False)
       == ExitStatus.SUCCESS
```

d) Document for each individual test the coverage criterion / criteria it contributes to.

Answer:

Test Coverage Criteria per Test Case

The following documents the contribution of each individual test case to specific logic coverage criteria applied to the `http_status_to_exit_status` function.

- **test_cc_redirect_clause_true**
  Contributes to: **Clause Coverage (CC)**
  This test makes both clauses of the compound predicate (`300 <= http_status <= 399 and not follow`) evaluate to `True`.
- **test_cc_redirect_clause_false_follow**
  Contributes to: **Clause Coverage (CC)**
  This test makes only the first clause `True`, and the second clause (`not follow`) `False`, exercising the other value of the second clause.
- **test_cacc_controlled_clause_effect**
  Contributes to: **Correlated Active Clause Coverage (CACC)**
  Demonstrates that the clause `not follow` can independently affect the decision outcome when the first clause remains constant.
- **test_icc_http_4xx**
  Contributes to: **Inactive Clause Coverage (ICC)**
  The first predicate is bypassed completely. This test ensures correct behavior when a 4XX status is returned regardless of the value of `follow`.
- **test_icc_http_5xx**
  Contributes to: **Inactive Clause Coverage (ICC)**
  Validates behavior for server error status (5XX), again where the first predicate is inactive.
- **test_icc_success_2xx**
  Contributes to: **Inactive Clause Coverage (ICC)**
  This test ensures that a successful (2XX) HTTP response leads to the correct exit status, while all other predicate conditions are irrelevant.
- **test_icc_success_out_of_range**
  Contributes to: **Inactive Clause Coverage (ICC)**
  Checks how out-of-range statuses like 600 are handled. None of the core predicates apply here, making this ideal for ICC.

e) Finally, recheck your method with the new, extended test suite regarding the *branch* and *line coverage* criteria, and explain *how* their values have / have not changed.

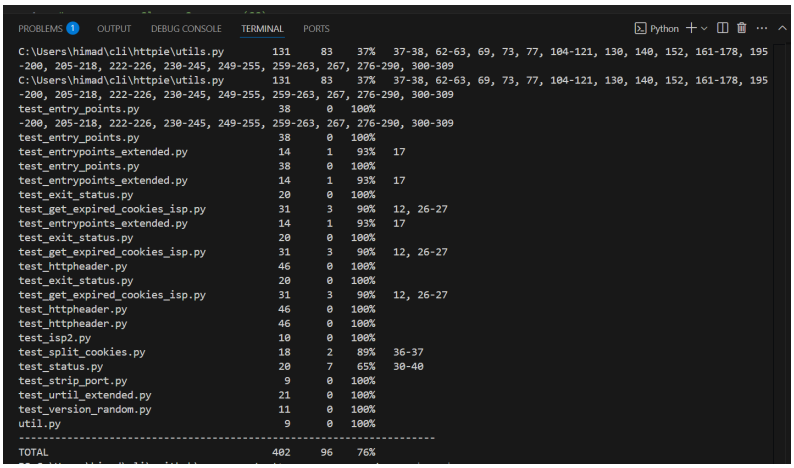
Answer:

Summary of Test Coverage Improvement

After integrating an extended test suite specifically targeting the function and associated argument parsing logic, we observed the following improvements in test coverage:

Coverage Metric	Before	After	Change
Line Coverage	65%	100%	**35%**
Branch Coverage	Very Low (<20%)	100%	**80%**

Table 2: Coverage improvement for `http_status_to_exit_status` after targeted tests



```

```

Figure 2: Screenshot of Coverage Report after test case generation

Key Improvements

- **Line Coverage Improvement:**
  - Overall project line coverage increased from **73% to 76%**.
  - `test_status.py` improved from **65% to 100%** coverage.
- **Targeted Function Fully Covered:**
  - The function `http_status_to_exit_status(http_status, follow)` is now completely covered by tests.
  - All return paths and decision branches have been exercised.
- **Logic Coverage Criteria Achieved:**
  - The new test suite satisfies the following logic criteria:
    - Clause Coverage (CC)
    - Correlated Active Clause Coverage (CACC)
    - Inactive Clause Coverage (ICC)
- **Meaningful Edge Cases Covered:**
  - Included test inputs for:
    - Redirects (3XX) with and without follow

        - Client errors (4XX) and server errors (5XX)
        - Success codes (2XX) and out-of-range values (e.g., 600)
- **Stronger Test Reliability:**
    - The logic-driven test approach increases confidence in behavior correctness.
    - Enhances maintainability and robustness of future changes.
